

The Challenge: Build a Rapid MVP

The Ask: Below are a few different app concepts. **Pick one** that sounds fun to you and build a lightweight MVP. Grab your favorite modern tools plug in a model of your choice, and show us what you've got.

What we are looking for:

- **Product Intuition:** How do you design the user experience? How do you handle loading states, empty states, and the overall "feel" of an AI interaction?
- **Execution:** Can you take a vague spec and make smart decisions to get a feature out the door as a proof of concept?
- **Deliverability:** We need to be able to use it easily. The ideal deliverable is a live URL we can just hit, OR a GitHub repo with a clear **README** where we can run some **run** command, drop in a single environment variable (like an OpenAI or Anthropic key), and run it locally without a fuss.

What we aren't looking for:

- **Over-engineering:** Don't worry about complex database architectures, auth, or enterprise-grade boilerplate.
- **Wasted weekends:** Please don't spend days on this. We are looking for a slick, rapid proof-of-concept, not a production-ready SaaS company. Have fun with it, show off your taste, and keep it scoped! We just want to be able to use the app and get an idea on how you approach a task like this.

AI

Using AI to complete this task is encouraged. We will want to hear about how you leveraged it and your approach from idea to delivered.

Feel free to include any artifacts that you used while working with the AI tools in development

Option 1: The "Spicy-to-Nice" Translator

The Concept: People often have valuable feedback, but it gets buried in emotional, blunt, or messy language. We want an app that takes raw, unfiltered venting and instantly turns it into a diplomatic, highly actionable piece of feedback.

The User Experience: The user pastes their frustrated rant into a text area. They should have a way to influence the output-perhaps by selecting the target audience (e.g., their manager, a direct report, or a customer) or the desired tone. The app then presents a newly polished version that keeps the core message but removes the "spice."

Things to think about:

- How do you keep the user engaged while the AI is generating the response?
 - What happens if they paste something extremely short, or completely unrelated to feedback?
 - How can you present the output so it's instantly useful? (e.g., highlighting what changed, or making it one-click to copy).
-

Option 2: The Landing Page Roaster

The Concept: Most software landing pages suffer from vague copy, confusing layouts, or weak calls-to-action. Build an app where a user uploads a screenshot of a landing page and gets a sharp, funny, but genuinely useful UX and copywriting critique.

The User Experience: The user uploads an image. They might choose how "brutal" they want the roast to be. The app then evaluates the image as a user would-looking at visual hierarchy, messaging, and clarity-and returns an entertaining teardown along with practical recommendations for improvement.

Things to think about:

- How do you handle the file upload process and ensure the user knows what's happening while the AI analyzes the image?
 - A wall of text can be boring. How might you structure the AI's critique so it's visually digestible (e.g., separating the "Roast" from the "Action Items")?
 - How do you guide the AI to actually understand the layout of a webpage from a flat image?
-

Option 3: The Bad Review Movie Poster

The Concept: Take a mundane or terrible customer review (e.g., *"The seagulls stole my chips and the pool was cold"*) and turn it into a dramatic, high-quality movie poster.

The User Experience: The user pastes a review into the app. They hit submit, and the app generates a highly stylized, cinematic movie poster based on the events described in the review. They could optionally select a genre, like "Disaster Movie," "Romantic Comedy," or "Gritty Reboot."

Things to think about:

- A user's raw text might not make a great image-generation prompt on its own. How might you use AI to interpret the text *first* before creating the final image?
 - Generating media can take a few seconds. How do you design an experience that feels fast and delightful even while the user is waiting?
 - How is the final asset presented to the user for them to admire or save?
-

Option 4: The Hype-Man Soundbite

The Concept: Text is great, but audio brings a different kind of energy. Enter a boring product update, a daily stand-up note, or a minor team win, and have the app generate a 10-second "hype" audio intro or spoken announcement.

The User Experience: The user types a brief, boring sentence like, *"I finally fixed the login bug."* The app takes that text, punches up the script to sound incredibly exciting, and produces an audio clip that the user can play back right in the browser.

Things to think about:

- How do you seamlessly move from text input to an audio playback experience?
- What controls might the user want over the audio? (e.g., choosing different personas, voices, or energy levels).
- How do you handle the user interface when audio is generating versus when it is ready to be played?
